Title: Meningitis Outbreak: New Reason to Turn to Chiropractic Care for Back Pain

Title Tag: Back Pain Sufferers Find New Reason to Turn to Chiropractic Care After Deadly Meningitis Outbreak

Meta Description: Following the recent fungal meningitis outbreak, some experts are now recommending chiropractic care as an alternative to surgery to relieve back pain.

Content: Even as outrage over the national fungal meningitis outbreak continues to mount, cooler heads are asking questions that could have long-term ramifications for the way we treat back pain.

Almost all of the hundreds of people who've died or been sickened received shots of what authorities now believe were contaminated steroid medication, traced to a since-closed Massachusetts compounding pharmacy, intended to relieve their back pain. That number is expected to grow as thousands more patients exposed to the tainted medication are tracked down.

The larger question being debated is this: With more than a quarter of adults experiencing back pain in any given three-month period, according to the National Institutes of Health, how safe – or even just financially worthwhile – are the plethora of expensive high-tech drugs, diagnostics and surgical interventions used to treat the condition? And could the far less invasive chiropractic care [www.yes2chiropractic.org] be a better alternative?

“These are one of the most overused procedures in the United States,” Dr. Steven J. Atlas, the director of Primary Care Research & Quality Improvement Network at Massachusetts General Hospital, told the Boston Globe regarding the prevalence of steroid injections.

And even many surgeons – whom Atlas has also previously criticized for being more interested in making money than counseling caution – now admit that some patients are actually worse off after going under the knife. This in the wake of a number of studies not only casting doubt on the benefit of such procedures as spinal fusion), but – in the case of the popular fracture-treating vertebroplasty – unequivocally recommending against it as the American Academy of Orthopedic Surgeons did in 2010.

All of that – plus the very real risks of overdosing on pain meds and relying on cortisone shots that can mask but not heal the pain – recently led to a groundbreaking decision by the University of Pittsburgh Medical Center-affiliated health plan that has proponents of chiropractic care feeling vindicated. Since January 2012, candidates for spine surgery among other things must first have gone through a three-month course of conservative management that includes the option of chiropractic therapy, an evidence-based approach involving manual and/or instrument manipulation of the spine as well as exercise, health and lifestyle counseling.

“There needs to be a safer way to address back pain,” says Dr. Gerard W. Clum, D.C., a spokesperson for the Foundation for Chiropractic Progress (www.yes2chiropractic.org). “These high-tech, invasive medical interventions are often worse than the disease, and don't seem to be getting individuals any closer to relief than they were decades ago.”
